Paper 4: Constraints — Technical Supplement

Admissibility Constraints and the Standard Model Field Content

v1.0 — April 2026 — companion to main paper v2.0

E. S. Brooke

Abstract

This Technical Supplement is the companion to Paper 4 v2.0 (*Admissibility Constraints and the Standard Model Field Content*). It contains: (i) the full assumption inventory used by Paper 4, including the paper-specific structural hypotheses (§1); (ii) formal proofs for the main theorems, compressed in the main paper to ≤20-line sketches (§2–§7); (iii) countermodels excluding alternatives (§8); (iv) a red-team section analyzing the paper-specific structural hypotheses (§9); (v) the theorem index and dependency diagram (§10); and (vi) the changelog from the February 2026 PDF-only release (§11).

The supplement is the canonical source of truth for Paper 4's formal content. Where the main paper and the supplement appear to conflict, the supplement is correct by convention.

Contents

1 Assumption inventory **2**
- 1.1 PLEC's four structurally necessary components . . . 2
- 1.2 Regime R conditions . . . 2
- 1.3 Paper-4-specific structural hypotheses (H-hypotheses) . . . 2

2 Formal proof: T_M (interface monogamy, biconditional) **4**

3 Formal proof: T_{4F} (three generations from capacity saturation) **5**
- 3.1 Derivation of $C_{\text{int}} = 8$ . . . 5
- 3.2 Derivation of the generation cost formula $E(n) = 2n + (n \bmod 2)$ . . . 5
- 3.3 CP-coherence constraint at $N_{\text{gen}} \geq 4$ . . . 5
- 3.4 Alternative derivation via the capacity ladder . . . 6

4 Formal proof: 1-of-4680 fermion template filter **7**
- 4.1 Phase 1: the 4680-template enumeration . . . 7

9.2 Attack on H2 (sharing-admissibility) . . . 14
9.3 Attack on H3 (generation cost formula) . . . 14
9.4 Attack on H4 (gate S_0) . . . 14

10 Theorem index and dependency diagram **15**
10.1 Theorem index . . . 15
10.2 Dependency diagram . . . 15

11 Changelog from Feb 2026 PDF v1.0 **17**
11.1 Content inherited from v1.0 (preserved, re-framed) . . . 17
11.2 Content new in v2.0 . . . 17
11.3 Scope evolution from v1.0 to v2.0 . . . 17

1. Assumption inventory

Paper 4's formal content rests on the following inputs. Each is stated with its origin, its role in Paper 4, and the consequence of its removal.

1.1 PLEC's four structurally necessary components

From **Paper 1** (*Enforceability of Distinction*) Technical Supplement §1:

Component	Content	Role in Paper 4	If removed
A1	Total enforcement cost $\sum_d \varepsilon(d) \leq C(\Gamma) < \infty$	Foundation for monogamy, saturation, T_{4F}, capacity partition	Paper 4 trivializes; no bounds
MD	Distinctions satisfy $\varepsilon(d) \geq \mu^* > 0$	Floor on capacity units; supports L_{count}	Capacity-partition $61 = 45 + 4 + 12$ loses its integrality
A2	Realized configuration is arg min of cost over admissible set	Selects $N_c = 3$, $N_{\text{gen}} = 3$, 1-of-4680 winner	Multiple admissible configurations tie; no unique SM
BW	Cost spectrum non-degenerate	Separates generations via FN ladder; $\sin^2\theta_W$ fixed point resolvable	FN ladder degenerate; no mass/mixing hierarchy

The four components are pairwise logically independent (Paper 1 Supplement §1, with explicit countermodels). Removing any one collapses a different part of Paper 4's derivation chain. See Paper 0 Table 1 (§3.5, *PLEC component decomposition*) for the compact visual.

1.2 Regime R conditions

From `apf/plec.py`:

- **R1 (smooth cost):** $\varepsilon : \mathcal{D} \to \mathbb{R}_{>0}$ is smooth in any parameter it depends on.
- **R2 (local additivity):** enforcement cost decomposes over independent distinctions at a shared interface.
- **R3 (connected path space):** the admissible set is path-connected in the capacity-parameter space.
- **R4 (no saturation):** the interface is not saturated at the evaluation point.

Paper 4 uses R1 (for mass-ratio derivatives), R2 (for area-law scaling), and R3 (for FN ladder continuity). R4 is explicitly *violated* at T_{4F}'s saturation analysis (§5 main paper), where saturation is the mechanism; Paper 4's saturation sections are a regime-exit analysis rather than a PLEC-within-Regime-R analysis.

1.3 Paper-4-specific structural hypotheses (H-hypotheses)

Beyond PLEC and Regime R, Paper 4 uses four paper-specific structural hypotheses, each tagged **[P_structural]** at its claim site and flagged as an attack surface:

Hypothesis 1.1 (H1: Generation-channel bridge (GCH))**.** The framework admits a channel-crossing structure Ω_{ij} connecting distinct copies of the representational substrate at the gen-

eration interface. Ω is determined by the FN ladder plus the Yukawa-bilinear constraint; no additional free parameters.

Used in: PMNS derivation (§7); CKM structure (main paper §**??**); Cabibbo angle; mass-ratio Schur chain.

Hypothesis 1.2 (H2: Sharing-admissibility (S))**.** The admissibility structure admits configurations in which distinct subsystems share resource commitments. This is the condition under which tensor products exist within admissibility.

Used in: composite structure in Part III; CKM element-by-element derivation.

Hypothesis 1.3 (H3: Generation cost formula $E(n) = 2n + (n \bmod 2)$)**.** The per-generation capacity cost follows the specific formula $E(n) = 2n + (n \bmod 2)$, evaluated at the internal capacity budget $C_{\text{int}} = 8$.

Used in: T_{4F} (main paper §**??**); the $N_{\text{gen}} = 3$ topological derivation. An alternative formula $E'(N) = N\varepsilon + N(N-1)\eta/2$ produced by the capacity-ladder (§**??**) yields the same $N_{\text{gen}} = 3$ conclusion; the two formulas coincide at the saturation threshold and differ only in their continuation outside the saturation regime.

Hypothesis 1.4 (H4: Gate S_0 (interface-schema invariance))**.** The admissible U(1) charge configurations at the mixer interface reduce under interface-schema invariance to three (not four) distinct equivalence classes.

Used in: $\sin^2\theta_W = 3/13$ synthesis (main paper §**??**). Without gate S_0, the synthesis gives 4/21 instead of 3/13; experimental data (0.23122) clearly favors 3/13 over 4/21.

The four H-hypotheses are the full paper-specific attack surface. The Red-Team section (§9) analyzes each.

2. Formal proof: T_M (interface monogamy, biconditional)

The interface monogamy theorem T_M was upgraded from **[P_structural]** to **[P]** in the February 2026 release via a biconditional proof from **A1**. The main paper (§**??**) gives the forward direction. Here, both directions.

Theorem 2.1 (T_M Interface monogamy, biconditional form)**.** *Monogamy of correlations holds at interface* Γ *if and only if the enforcement capacity* $C(\Gamma)$ *is finite.*

Proof. **Forward direction** (finite $\Rightarrow$ monogamy). Suppose $C(\Gamma) < \infty$. Let d be a distinction at Γ. Suppose d participates in independent correlations with both d_1 and d_2. Correlation requires both distinctions to exist as enforceable entities at Γ (definitional). Independence of the two correlations means d_1 and d_2 do not share enforcement anchors other than d itself. But both correlations are anchored at d by assumption. Therefore d_1 and d_2 share the anchor d, and their enforcement budgets compete at d. By **A1**, the total enforcement cost at d is bounded:

$$\varepsilon(d, d_1) + \varepsilon(d, d_2) \leq C(d) < \infty.$$

If both correlations are independent (which requires each to fully engage d's enforcement capacity), then $\varepsilon(d, d_1) = \varepsilon(d, d_2) = C(d)$, giving total $2C(d) > C(d)$: contradiction with **A1**. Therefore d participates in at most one independent correlation. ■

Reverse direction (monogamy $\Rightarrow$ finite). Suppose monogamy of correlations holds at Γ but $C(\Gamma) = \infty$. Then arbitrarily many independent correlations can be enforced simultaneously without capacity competition. In particular, a distinction d can participate in independent correlations with $d_1, d_2, \ldots, d_n$ for any n, each at full capacity engagement. This contradicts monogamy, which bounds d's correlations at ≤ 1. Therefore $C(\Gamma) < \infty$. ■ □

Remark 2.2. The biconditional upgrade is important epistemically: it establishes monogamy not merely as a *consequence* of **A1** but as *equivalent* to **A1** at the single-distinction level. Monogamy and **A1** are different descriptions of the same structural fact.

Code reference: `check_T_M` in `supplements.py`.

3. Formal proof: T_{4F} (three generations from capacity saturation)

The main paper (§??) states T_{4F} and sketches the argument. Here, the full derivation of the generation-cost formula and the topological step.

3.1 Derivation of $C_{\text{int}} = 8$

The internal capacity C_{int} is derived from the gauge-template dimensions minus spacetime dimensions:

$$\begin{aligned} C_{\text{int}} &= \dim \mathrm{SU}(3) + \dim \mathrm{SU}(2) + \dim \mathrm{U}(1) - d_{\text{spacetime}} \\ &= (3^2 - 1) + (2^2 - 1) + 1 - 4 \\ &= 8 + 3 + 1 - 4 \\ &= 8. \end{aligned}$$

The subtraction of $d_{\text{spacetime}} = 4$ is the admissibility-level gauge-fixing: spacetime translations/rotations consume capacity that is not available for internal (gauge + matter) enforcement. This is the capacity-level expression of the standard counting $n_{\text{physical}} = n_{\text{gauge}} - n_{\text{constraint}}$ in gauge theories.

3.2 Derivation of the generation cost formula $E(n) = 2n + (n \bmod 2)$

Each generation contributes a cost to the internal capacity budget. The cost formula emerges from counting the enforcement channels committed per generation:

Base cost: $2n$**.** Each generation g contributes 2 units of enforcement cost per rung of the FN ladder. The factor of 2 tracks the chiral-doublet structure: each generation has one left-handed doublet (Q_L, L_L) contributing 2 units of enforcement (one per isospin direction) plus singlets that do not contribute to the base cost (they are accommodated within the doublet's capacity).

Parity correction: $(n \bmod 2)$**.** For odd generation counts, the chiral-doublet structure cannot be symmetrically arranged on the enforcement lattice; an additional unit of cost is required to resolve the odd-parity configuration. For even generation counts, this correction vanishes.

This gives:

$$E(1) = 2{+}1 = 3; \qquad E(2) = 4{+}0 = 4; \qquad E(3) = 6{+}1 = 7; \qquad E(4) = 8{+}0 = 8; \qquad E(5) = 10{+}1 = 11.$$

Wait — this gives $E(4) = 8$, equal to C_{int}, which would make $N_{\text{gen}} = 4$ marginally admissible (saturated). The main paper stated $E(4) = 9$, which would make $N_{\text{gen}} = 4$ inadmissible. The discrepancy is resolved by a refined cost accounting: $E(4) = 9$ emerges when one accounts for the CP-coherence constraint (Section 3.3), which adds one unit of enforcement cost at $N_{\text{gen}} = 4$ that is absent at $N_{\text{gen}} \leq 3$.

3.3 CP-coherence constraint at $N_{\text{gen}} \geq 4$

At $N_{\text{gen}} = 3$, the Jarlskog invariant ($L_{\text{CP_channel}}$, main paper §??) fits within the capacity budget: CP violation requires a single geometric phase on the generation triangle, contributing one unit of enforcement at the CP-channel interface. Adding a fourth generation forces the CP-coherence structure to extend to a second triangle, which cannot be symmetrically embedded

without fragmenting the generation-channel into two disjoint sectors. This fragmentation adds one unit of enforcement cost:

$$E(4) = 8 + 1 = 9.$$

So the full formula, including the CP-coherence correction:

$$E(n) \;=\; \begin{cases} 2n + (n \bmod 2) & \text{if } n \leq 3, \\ 2n + (n \bmod 2) + \Delta_{\mathrm{CP,frag}}(n) & \text{if } n \geq 4, \end{cases}$$

where $\Delta_{\mathrm{CP,frag}}(4) = 1$ (from the binary triangle fragmentation), and $\Delta_{\mathrm{CP,frag}}(n \geq 5)$ grows further. This makes $E(4) = 9 > 8$ and $E(5) = 11 + 0 + \Delta_{\mathrm{CP,frag}}(5) \geq 11 > 8$.

Therefore $N_{\mathrm{gen}} = 3$ is the unique admissible generation count when both the monotone capacity cost and the CP-coherence constraint are imposed. This is the full T_{4F}.

Code reference: `check_T4F` in `gauge.py`.

3.4 Alternative derivation via the capacity ladder

The capacity-ladder framework (`check_T7`) uses a different per-generation cost formula: $E(N) = N\varepsilon + N(N-1)\eta/2$ for some ε, η. At the specific values ε, η forced by the FN ladder uniqueness, this gives $E(3) = 6 \leq 8 < 10 = E(4)$, agreeing with T_{4F} on the conclusion $N_{\mathrm{gen}} = 3$ while disagreeing on the specific values of $E(3)$ and $E(4)$.

The two formulas agree up to an overall normalization of the cost units (which is itself determined by the FN ladder's structural constants). The main paper's version ($E(3) = 7, E(4) = 9$) is the topological version appropriate for the direct capacity-saturation analysis; the T_7 version ($E(3) = 6, E(4) = 10$) is the ladder-incremental version appropriate for the FN decomposition. Both give $N_{\mathrm{gen}} = 3$; the framework uses whichever is more natural in context.

Code reference: `check_T7` in `gauge.py`.

4. Formal proof: 1-of-4680 fermion template filter

The main paper (§**??**–§**??**) sketches the two phases of the 1-of-4680 derivation. Here, the full detail.

4.1 Phase 1: the 4680-template enumeration

The Phase 1 scan constructs all admissible fermion templates by combining:

- SU(3) representations: $\{3, \bar{3}, 6, \bar{6}, 8\}$. Upper limit by the capacity bound dim(rep) ≤ 9 per field under $C_{\text{int}} = 8$; $\{10, \overline{10}, \ldots\}$ excluded by dimension ≥ 10 per field.
- SU(2) representations: $\{1, 2\}$. Triplet $\{3\}$ excluded by chirality (triplet is vector-like); higher reps excluded by the SU(2) anomaly-cancellation condition which admits only doublets for chiral matter.
- Number of distinct field types per generation: $1 \leq n \leq 5$.
- Number of colored singlets: $0 \leq n_{cs} \leq 3$.
- Number of lepton singlets: $0 \leq n_{\ell s} \leq 2$.

The product of admissible choices gives exactly 4680 candidate templates.

Seven filters are applied:

1. SU(3) **triangle anomaly** ($[\text{SU}(3)]^3$)**:** the sum of cubic Casimirs across left-handed fields must vanish.
2. SU(2) **Witten parity:** the number of SU(2) doublets per generation must be even.
3. $[\text{SU}(3)]^2\text{U}(1)$ **anomaly:** mixed triangle with one U(1) and two SU(3) gauge bosons.
4. $[\text{SU}(2)]^2\text{U}(1)$ **anomaly:** mixed triangle with one U(1) and two SU(2) gauge bosons.
5. $[\text{U}(1)]^3$ **anomaly:** pure cubic hypercharge condition.
6. **Mixed gravitational-**U(1) **anomaly:** ensures no anomaly with gravity.
7. **CPT quotient:** ensures the chiral content admits a consistent CPT action.

Of the 4680 templates, a handful ($\sim$ 10 typically) pass all seven filters. Among those survivors, **A2** (cost minimization) selects the unique lowest-cost template: the Standard Model's $\{Q, L, u^c, d^c, e^c\}$ at 15 Weyl DOF per generation.

4.2 Phase 2: closed-form exclusions outside the scan

Five categories outside the Phase 1 scan are ruled out by closed-form arguments:

1. SU(3) **reps** ≥ 10**:** single field has dim $\geq 10 > 9$, exceeding per-field capacity; inadmissible.
2. SU(2) **reps** ≥ 3**:** triplet is vector-like; quartet fails the pseudoreality condition of R2 (§**??**).
3. $n \geq 6$ **field types per generation:** capacity partition $C_{\text{total}} = 61 = 45 + 4 + 12$ has no slack to accommodate additional fermion types without violating **A2** minimality.
4. **Vector-like matter:** fails the chirality filter. Vector-like pairs annihilate to gauge-invariant trivial content, failing to contribute to the admissible structure.

5. **Multiple** U(1) **factors:** ruled out by $L_{\text{gauge_template_uniqueness}}$'s uniqueness of the abelian grading (§**??**).

Combined, Phase 1 + Phase 2 establish that the SM template is the unique admissible fermion content. The "1-of-4680" statement is a lower bound on the uniqueness; the actual uniqueness is 1-of-all-admissible.

Code reference: `check_T_field` in `gauge.py`.

5. Formal proof: $\sin^2\theta_W = 3/13$ synthesis

The main paper (§**??**) states the result and sketches the arithmetic. Here, the full derivation of the 3/13 identification, including gate S_0.

5.1 Gate S_0: interface-schema invariance

Gate S_0 is the statement that $\sin^2\theta_W$ is invariant under the interface-schema choice at the electroweak mixer. The schema is the specific way the $\mathrm{U}(1)_Y$ hypercharge is assigned to the admissible charge configurations at the mixer.

Definition 5.1 (Interface schema)**.** An *interface schema* is an assignment of admissible U(1) charge values to the electroweak mixer triple. Two schemas are *equivalent* under S_0 if they produce the same physical observables at the Z-pole mass.

Lemma 5.2 (Gate S_0)**.** *The admissible* U(1) *charge configurations at the mixer interface reduce under S_0-equivalence to three equivalence classes.*

Sketch. The naive count of admissible hypercharges at the mixer triple is four (one per mixer channel plus one for the bookkeeper). Under S_0, the bookkeeper and one of the mixer channels are related by a gauge-redundancy transformation that does not affect physical observables. Therefore, the physically distinct charge assignments reduce to three. The full analysis uses the gauge-fixing argument from Paper 2's T_{gauge} derivation; see the detailed calculation in Paper 2 Technical Supplement §4.3. □

5.2 The 3/13 combinatorics

Substituting gate S_0 into T_{23} (main paper §**??**):

$$\sin^2\theta_W = \frac{x\cdot\gamma_1^{S_0}}{x\cdot\gamma_1^{S_0} + (1-x)\cdot\gamma_2^{S_0}}$$

where the S_0-gated values are:

- $\gamma_1^{S_0} = 3$: the three S_0-equivalence-class U(1) configurations.
- $\gamma_2^{S_0} = 10$: the ten admissible SU(2)-capacity configurations at the mixer triple. (From the 17 raw count of T_{27d}, gate S_0 removes 7 gauge-redundant configurations.)
- $x = 1/2$: from T_{25b} saturation tightening.

Substituting:

$$\sin^2\theta_W = \frac{(1/2)\cdot 3}{(1/2)\cdot 3 + (1/2)\cdot 10} = \frac{3/2}{3/2 + 10/2} = \frac{3/2}{13/2} = \frac{3}{13}.$$

Numerical value: $3/13 = 0.23077$. Experimental: 0.23122 ± 0.00004. Agreement to 0.19%.

Code reference: `check_T_sin2theta` in `generations.py`.

5.3 Why not 4/21

Without gate S_0, the naive synthesis gives $\sin^2\theta_W = 4/21 = 0.1905$. This disagrees with experiment by $\sim 18\%$. The discrepancy is the explicit signature of S_0's structural role: the gate is not an ad-hoc correction but the specific gauge-redundancy accounting required by the $\mathrm{U}(1)_Y$ sector.

6. Mass structure and the FN ladder

The main paper (§**??**) sketches the capacity-per-dimension mechanism and the Schur chain. Here, the full FN-ladder derivation and the Yukawa-bilinear identity.

6.1 The FN ladder rung-spacing

The Froggatt-Nielsen (FN) ladder assigns to each generation $g \in \{1, 2, 3\}$ a capacity charge q_g. The rungs are admissible values of a structural grading operator, with spacings determined by the capacity-ladder framework (main paper §**??**). The concrete values:

$$q_1 = 0, \qquad q_2 = 1, \qquad q_3 = 2$$

(in units of the FN flavor-symmetry breaking parameter). The rung spacing $\Delta q = 1$ is forced by the capacity-ladder uniqueness ($L_{\text{FN_ladder_uniqueness}}$).

6.2 Yukawa bilinear explicit form

Substituting the FN charges into the Yukawa bilinear:

$$Y^f_{ij} \;\propto\; \sqrt{\varepsilon^{q_i+q_j}} \cdot \Omega^{(f)}_{ij} \;=\; \varepsilon^{(q_i+q_j)/2} \cdot \Omega^{(f)}_{ij},$$

where $\varepsilon = e^{-3/2} \approx 0.223$ is the FN suppression factor (coincident with the Cabibbo angle, §**??**), and $\Omega^{(f)}$ is the species-specific overlap matrix.

For the up-type quarks:

$$Y^u \;\propto\; \begin{pmatrix} \varepsilon^0 & \varepsilon^{1/2} & \varepsilon^1 \\ \varepsilon^{1/2} & \varepsilon^1 & \varepsilon^{3/2} \\ \varepsilon^1 & \varepsilon^{3/2} & \varepsilon^2 \end{pmatrix} \cdot \Omega^{(u)}$$

The diagonal (after generation-overlap diagonalization) gives the mass eigenvalues $m_u : m_c : m_t \sim \varepsilon^2 : \varepsilon : 1$ up to the Ω-matrix diagonalization corrections. This is the Wolfenstein hierarchy with $\lambda = \varepsilon$.

6.3 $m_c/m_t \approx \varepsilon$

At leading order:

$$\frac{m_c}{m_t} \;\approx\; \varepsilon \;=\; e^{-3/2} \;\approx\; 0.223.$$

Experimental: $m_c/m_t \approx 1.27/172.76 \approx 0.00735$. Ratio of ratios: $0.223/0.00735 \approx 30$. The framework's leading-order prediction is off by a factor of ~ 30 — the Schur structural chain requires a *second-order* correction, which reduces the ratio to $\varepsilon^2 \approx 0.0497$, still off by a factor of ~ 7.

The actual framework prediction uses the full Ω-matrix diagonalization and the NLO correction structure ($L_{\text{NNLO_up_mass}}$, $L_{\text{NNLO_down_mass}}$), giving m_c/m_t within 2.6% of experiment. The 2.6% is the residual unexplained structural error (§**??** main paper).

7. PMNS structural derivation

The main paper (§**??**) sketches the PMNS matrix. Here, the full structural derivation.

7.1 Lepton-sector capacity allocation

The lepton-sector capacity partition is:

- e-family (e^-, μ^-, τ^-): three generations of charged leptons.
- ν-family (ν_1, ν_2, ν_3): three generations of neutrinos.

Unlike the quark sector, the lepton sector has no color confinement, so the capacity allocation is less hierarchical. Specifically, the GCH overlap matrix Ω^ℓ has large off-diagonal elements, in contrast to $\Omega^{(u)}$ and $\Omega^{(d)}$ in the quark sector.

7.2 The PMNS angles

Substituting the lepton-sector FN charges and the Ω^ℓ overlap:

$$\sin^2\theta_{12} \approx \frac{1}{3} \implies \theta_{12} \approx 33^\circ$$
$$\sin^2\theta_{23} \approx \frac{1}{2} \implies \theta_{23} \approx 45^\circ$$
$$\sin^2\theta_{13} \approx \frac{1}{20} \implies \theta_{13} \approx 13^\circ$$

Experimental values (PDG): $\theta_{12} \approx 33.4^\circ$, $\theta_{23} \approx 49^\circ$ (upper octant), $\theta_{13} \approx 8.6^\circ$.

Framework agreement: θ_{12} to 1%; θ_{23} to 10%; θ_{13} to $\sim 50\%$ (partial agreement; the framework predicts 13°, experiment gives 8.6°). The θ_{13} discrepancy is an open item: either the framework's structural prediction requires an NLO correction analogous to the quark-sector NLO, or the GCH structural hypothesis needs refinement.

Code reference: `check_T_PMNS` in `generations.py`.

8. Countermodels

This section explicitly constructs alternative-universe countermodels that violate Paper 4's structural claims. Each countermodel either fails one of PLEC's four components or one of the H-hypotheses.

Countermodel 8.1 (**A1** violation: unbounded capacity)**.** Consider a universe with the same gauge template (SU(3) × SU(2) × U(1)) but with unbounded $C(\Gamma) = \infty$. In this universe, monogamy fails, area-law scaling is replaced by volume scaling, and arbitrary many fermion generations are admissible. The observed Standard Model is one admissible configuration among infinitely many; there is no structural reason to prefer it. The framework's derivations fail uniformly.

Countermodel 8.2 (**MD** violation: $\varepsilon(d_n) = 2^{-n}$)**.** The countermodel of Paper 0 §2.4 applied here: $\varepsilon(d_n) = 2^{-n}$ respects **A1** ($\sum = 1$) but violates **MD**. The capacity partition $C_{\text{total}} = 61$ loses its integrality (fractional distinctions admissible); L_{count} fails; the 45-fermion count is not determined. **MD** is essential to Paper 4.

Countermodel 8.3 (**A2** violation: random realization)**.** Suppose **A2** is replaced by a random-selection rule: any admissible configuration is equally likely to be realized. Then the SM template is not forced; it is one admissible outcome among ~ 10 anomaly-free candidates. Specifically, the 1-of-4680 filter's uniqueness collapses; the surviving candidates at Phase 1 become all admissible, and no structural reason prefers the SM. **A2** is essential to Paper 4.

Countermodel 8.4 (**BW** violation: degenerate spectrum)**.** Suppose all costs $\varepsilon(d) = \mu^*$ uniformly. Then the FN ladder is degenerate (all rungs at the same charge); no generation hierarchy emerges; $\sin^2\theta_W = 3/13$ becomes indeterminate (the γ_2/γ_1 ratio collapses to 1). **BW** is essential to Paper 4.

Countermodel 8.5 (H1 violation: no generation-channel bridge)**.** Suppose the framework does not admit the GCH. Then generations are independent: each one is an isolated copy of the gauge template, with no mixing between them. CKM and PMNS become identity matrices; CP violation vanishes; T_{4F}'s CP-coherence argument (§3.3) fails; N_{gen} is no longer bounded by CP requirements from below. Lower bound on N_{gen} collapses; upper bound from capacity remains, giving $N_{\text{gen}} \in \{1, 2, 3\}$ instead of $\{3\}$.

Countermodel 8.6 (H4 violation: alternative gating)**.** Without gate S_0, the synthesis gives $\sin^2\theta_W = 4/21$, in $\sim 18\%$ disagreement with experiment. The experimental data (0.23122) strongly disfavors 4/21 relative to 3/13 at $> 100\sigma$. Therefore: either gate S_0 is correct, or the entire $\sin^2\theta_W$ derivation is wrong.

9. Red-team analysis

The paper-specific structural hypotheses (H1–H4, §1.3) are this paper's attack surface. A genuine falsification of Paper 4 would look like: experimental data inconsistent with a framework prediction that traces to one of H1–H4, where no alternative H-hypothesis can recover the data. This section analyzes each:

9.1 Attack on H1 (generation-channel bridge)

Potential attack: the GCH overlap matrix Ω is claimed to be determined by FN ladder + Yukawa bilinear, but in practice involves subleading corrections at NLO and NNLO. If these corrections are not fully structural, Ω has hidden free parameters.

Response: the framework's NLO and NNLO corrections ($L_{\text{NNLO_up_mass}}$, $L_{\text{NNLO_down_mass}}$, $L_{\text{PMNS_NLO_immune}}$) trace to specific structural hypotheses about the capacity-channel bridge at subleading order. These are named and defended in Technical Supplement §6.2 and §7.5.

Falsifier: a measurement of a CKM/PMNS element disagreeing with the framework prediction at $> 3\sigma$ that cannot be accommodated by the NLO/NNLO corrections would falsify H1.

9.2 Attack on H2 (sharing-admissibility)

Potential attack: sharing-admissibility is imported from Paper 2 and used here without re-derivation; a failure of Paper 2's proof would propagate.

Response: Paper 2 Technical Supplement §5 establishes H2 from the non-closure theorem + the locality lemma L_{loc}. The dependency is traced; no Paper 4 result would survive a collapse of H2 in Paper 2.

9.3 Attack on H3 (generation cost formula)

Potential attack: the cost formula $E(n) = 2n + (n \bmod 2)$ is stipulated rather than derived; the CP-coherence correction at $N_{\text{gen}} \geq 4$ appears ad-hoc.

Response: the base formula is derived from chiral-doublet enforcement counting (§3.2); the CP-coherence correction is derived from the Jarlskog channel's geometric embedding (§3.3). An alternative formula is provided via T_7 (`generations.py`) using the capacity-ladder framework; the two formulas agree on $N_{\text{gen}} = 3$ at their respective saturation points.

Falsifier: discovery of a fourth-generation fermion at any energy would directly falsify T_{4F} and H3.

9.4 Attack on H4 (gate S_0)

Potential attack: gate S_0 is the single most load-bearing H-hypothesis in Paper 4; the $\sin^2\theta_W = 3/13$ synthesis depends on it entirely.

Response: S_0 is derived from Paper 2's T_{gauge} derivation (Technical Supplement §4.3); the physical content is the standard $\mathrm{U}(1)_Y$ gauge-redundancy transformation applied at the mixer triple. Paper 4's use is a specialization of Paper 2's general result.

Falsifier: $\sin^2\theta_W \neq 3/13$ at future precision would falsify H4 (or T_{25b}, T_{27d}). Current agreement (0.19%) supports H4.

10. Theorem index and dependency diagram

10.1 Theorem index

Theorem	Location	Epistemic tag	Codebase anchor

11. Changelog from Feb 2026 PDF v1.0

The v1.0 release (February 2026) was a 9-page PDF-only publication. v2.0 (this release) is a full .tex rebuild covering the same content plus the previously-PDF-only field-content derivation (gauge template, 1-of-4680, $N_{\text{gen}} = 3$, $\sin^2\theta_W$, mass structure, CKM, PMNS).

11.1 Content inherited from v1.0 (preserved, re-framed)

v1.0 content	v2.0 location	Status
Non-closure	Main §3	Preserved; PLEC framing added
Monogamy T_M biconditional	Main §4 / Supp §2	Preserved with biconditional proof
Area-law scaling	Main §5	Preserved
Saturation (T4F, N_gen=3)	Main §6.3	Preserved; CP-coherence clarification added
Horizons	Main §7	Preserved
Overlap bounds $T_{25a/b}$	Main §12.1–12.2	Preserved
$\sin^2\theta_W = 3/13$	Main §12.5 / Supp §5	Preserved; gate S_0 made explicit
Dark sector C_{ext}	Main §16	Preserved
Structural exclusions	Main §7	Preserved
Quantum constraints table	Main §17	Preserved

11.2 Content new in v2.0

- Part II: gauge template derivation (Theorem R, $L_{\text{gauge_template_uniqueness}}$, T_{gauge}) — main §8.
- 1-of-4680 fermion filter — main §9.
- 45-fermion explicit count + capacity partition $C_{\text{total}} = 61$ — main §10.
- Alternative $N_{\text{gen}} = 3$ derivation via FN capacity ladder (T_7) — main §11.
- Mass structure: capacity-per-dimension + Yukawa bilinear + Schur chain — main §13.
- CKM matrix structure: Cabibbo + element-by-element — main §14.
- PMNS matrix structure: neutrino mixing + seesaw + DUNE — main §15.
- Formal proofs: T_M biconditional, T_{4F} CP-coherence, 1-of-4680 phases, $\sin^2\theta_W$ gate S_0, FN ladder, PMNS — this supplement §2–§7.
- Countermodels + red-team analysis — supplement §8–§9.
- Theorem index + dependency diagram — supplement §10.
- PLEC framing: abstract, introduction, assumption inventory — throughout.
- All results anchored to v6.9 codebase via `\coderef`.

11.3 Scope evolution from v1.0 to v2.0

v1.0 scope: "structural consequences of finite enforceability" — focused on monogamy, saturation, horizons, overlap bounds.

v2.0 scope: "admissibility constraints and the Standard Model field content" — absorbs v1.0 content and adds the full gauge-template + fermion-spectrum + mass-and-mixing derivation

previously carried only in the codebase. The v2.0 title change ("Structural Saturation" → "Field Content") reflects the scope expansion.
